APPELLANT'S BRIEF

I. Real Party in Interest

The real party in interest is Baker Hughes Incorporated.

II. Related Appeals and Interferences

There are no related appeals or interferences.

III. Status of the Claims

Claims 1, 2, 4-7, 9 and 12-14 are finally rejected and are the subject of this appeal.

Claims 10, 11 and 15-17 are allowed.

Claim 3 and 8 are canceled.

IV. Status of Amendments

A Second Amendment after Final Rejection was mailed October 27, 2006 and was entered in an Advisory Action mailed November 16, 2006. This Advisory Action incorrectly listed claims 5 and 9 as still being objected to because the entered Second Amendment after Final Rejection cured the objections to claims 5 and 9. Claim 8 was canceled in this amendment.

V. Summary of the Claimed Subject Matter

In the only rejected independent claim in this appeal, claim 1, is graphically illustrated in FIG. 4 where the base pipe 10 is expanded into the screen 14 by a swage 20 to secure the two together. The base pipe is inserted in the screen and the base pipe is expanded from within until the two become attached to each other. This is described in the specification on page 3 in paragraph 15.

VI. Grounds for Rejection to be Reviewed on Appeal

1. Are claims 1, 2, 4, and 6-8 anticipated under §102 by Echols USP 6,941,652?

2. Are claims 12-14 obvious under §103 in view of Echols USP 6,941,652?

VII. Argument

a) Are claims 1, 2, 4, and 6-8 anticipated under §102 by Echols USP 6,941,652?

This is a very simple case. Claim 1 is a two step method: inserting a base pipe into a filter layer and attaching them together by expansion of the base pipe. That's it!

Yet the problem during prosecution that has made this appeal necessary is that the Examiner has failed to recognize the difference between taking a fully assembled screen that has a base pipe and filter layer already assembled to each other and running the assembly in the well and expanding that assembly downhole, on the one hand, and, on the other hand, taking a base pipe and expanding it into a filter layer to initially assemble the screen before running it in the well.

In the former, the assembled filter is expanded downhole to reduce or eliminate an annular space around the screen to reduce the extent of the need to pack such annular space with gravel as a filtration aid or, better yet to eliminate that need altogether. Applicant doesn't dispute that the Echols reference teaches the expansion from within the base pipe of an assembled screen assembly 36 after it is run down the wellbore. As stated in column 4 lines 49-55:

The well screen 36 may be radially expanded utilizing any of various methods. For example, a swage may be passed through the base pipe 38, fluid pressure may be applied to a membrane positioned within the base pipe, etc. Thus, any method of expanding the well screen 36 may be used without departing from the principles of the present invention.

However, the Examiner has steadfastly refused to acknowledge that this expansion is occurring downhole after the screen assembly has been built and run

downhole. Claim 1 is about how to build a screen and not about what to do with it once it is built and run in the wellbore.

The Echols reference talks about how the screen assembly 36 is put together. First, as shown in FIG. 2, an outer shroud 42a for the screen assembly 36 is laid flat and an assembly of screen layers 48-52 are placed on top and preferably attached by diffusion bonding (column 5 line 55 to column 6 line 21).

Then, the flat sheet is trimmed to a dimension and rolled into a tube and seam welded at 56, as shown in FIG. 3. The screen material 40 is now in the interior of this tube structure (column 6 lines 22-32).

Then, the base pipe 38, FIG. 4, is inserted into the tube, FIG. 3, made up of shroud 42 with the filter layers 40a already attached to it. Welds 58, FIG. 5, attach the base pipe to the FIG.3 assembly of the jacket with the screen layers inside of it. Here's how the specification (column 6 lines 33-41) describes this, the actual method of assembly of the screen in Echols:

"After the fabrication of the shroud 42 is completed, the perforated tubular base pipe 38 (see FIG. 4) is telescoped into the interior of the shroud 42 (see FIGS. 5 and 6), thereby sandwiching the filter media 40 between the base pipe 38 and the shroud 42 (see FIGS. 6 and 7). The filter media-lined shroud 42 is then suitably anchored to the base pipe 38, such as by annular welds 58 (see FIG. 5) extending around the opposite ends of the shroud 42."

The present application paragraph 2 describes that using welding is a bad thing as in service these welds tended to fail. The Echols reference discusses base pipe expansion but not in context of avoiding connections known to fail downhole as disclosed in the application. Echols goes directly for the welding solution of securing the filter material to the base pipe despite his knowledge that techniques exist for base pipe expansion of the finished screen assembly downhole. In essence, Echols teaches away from the claimed

method of assembling a screen assembly by failing to recognize that expansion of the base pipe is a technique to attach a screen layer to it. As a result of the claim 1 method, the finished product is serviceable downhole, particularly when the assembly is expanded downhole and under conditions where the base pipe is under large tension loads that would otherwise have caused weld failure if the Echols technique of fabrication were used. Large differential pressures on the screen can cause it to flex breaking welded connections in the Echols design. Expansion of the base pipe to connect it to the surrounding screen assembly solves this screen construction problem. These issues in initial screen assembly fabrication are totally unrecognized in Echols despite the fact that he discusses expansion of the fully assembled screen after it is run downhole.

b) Are claims 12-14 obvious under §103 in view of Echols USP 6,941,652?

The Examiner repeatedly points to column 5 lines 1-4 where it states as follows:

“It will be readily appreciated that, when the base pipe 38 is expanded radially outwardly, the filter media 40 will be radially compressed between the shroud 42 and the base pipe 38.”

This portion of the specification describes what happens when the already assembled screen assembly is run down the wellbore and expanded there as part of a tubing string. This is not done when the base pipe is attached to the screen tube into which it is inserted during initial fabrication. Claim 1 is about the initial fabrication. The Examiner jumps around the Echols reference giving it a meaning that is not there by virtue of his confusion between the disclosed Echols method of running the finished product and the Echols method of fabrication of the underlying product. Claim 1 is about how to fabricate the underlying product. The Echols reference, when properly applied to claim 1, requires reading of columns 5-6 where the fabrication method is described. In

the end, the Echols product suffers from the failures for welded connections in fabrication described in paragraph 2 of the present application. In no way does the Echols initial fabrication method teach using expansion of the base pipe to secure it to the screen that surrounds it

Claim 1 and all the claims that depend on it are novel and unobvious over Echols.

Respectfully submitted,

05/11/2007

VIII. Claims Appendix

1. A method of manufacturing a screen for downhole use, comprising:
inserting a base pipe into a filter layer;
securing said filter layer to said base pipe by expanding said base pipe.
2. The method of claim 1, comprising:
creating an interference fit between said base pipe and said filter layer.
4. The method of claim 1, comprising:
reducing the size of said filter layer.
5. The method of claim 1, comprising:
accomplishing said securing said filter layer to said base pipe without welding,
adhesives or mechanical connectors.
6. The method of claim 1, comprising:
inserting said base pipe and filter layer downhole;
expanding said base pipe downhole.
7. The method of claim 1, comprising:
mounting a protective jacket to said filter layer before inserting said base pipe.
9. The method of claim 2, comprising:
accomplishing said securing said filter layer to said base pipe without welding,
adhesives or mechanical connectors.
12. The method of claim 1, comprising:
expanding said base pipe for at least a portion of the length of said filter layer.
13. The method of claim 12, comprising:
expanding said base pipe near the ends of said filter layer.

14. The method of claim **12**,comprising:
- expanding said base pipe for the entire length of said filter layer and beyond.

IX. Evidence Appendix

Appellant relies on the Echols USP 6,941,652 made of record by the Examiner.

METHODS OF FABRICATING A THIN-WALL EXPANDABLE WELL SCREEN ASSEMBLY

CROSS-REFERENCE TO RELATED APPLICATION

This application is a continuation of U.S. application Ser. No. 10/109,154, filed on Mar. 28, 2002 now U.S. Pat. No. 6,619,401 and entitled "METHODS OF COMPLETING A SUBTERRANEAN WELL", which was a division of U.S. application Ser. No. 09/574,658, filed on May 18, 2000 now U.S. Pat. No. 6,415,509 and entitled "METHODS OF FABRICATING A THIN-WALL EXPANDABLE WELL SCREEN ASSEMBLY" (As amended), such applications being hereby incorporated by reference herein in their entireties. Further, this application discloses subject matter similar to that disclosed in copending U.S. application Ser. No. 09/565,899 filed on May 5, 2000, entitled "EXPANDABLE WELL SCREEN", and having Ana M. Castano-Mears, John C. Gano and Ralph H. Echols as inventors. Such copending is also hereby incorporated by reference herein in its entirety.

BACKGROUND OF THE INVENTION

The present invention generally relates to filtration apparatus and, in a preferred embodiment thereof, more particularly relates to a specially configured expandable well screen assembly for use in a subterranean wellbore, and associated methods of fabricating the well screen.

It is useful in some circumstances to be able to convey generally tubular equipment into a subterranean wellbore to a predetermined location therein, and then outwardly expand the equipment in the wellbore. For example, a restriction in the wellbore may prevent the equipment in its expanded configuration from passing through that part of the wellbore, but the equipment may pass through the restriction in its retracted configuration. In one application of this principle, it is known to use expandable well screens in wellbores.

An example of the potential usefulness of expandable equipment in a wellbore is where the wellbore intersects a productive, relatively unconsolidated formation. It is desirable in many situations to be able to utilize a well screen to filter production fluid from the formation, while foregoing the expense of cementing casing in the wellbore and performing a gravel packing operation. Unfortunately, without any radial support the unconsolidated formation would likely collapse into the wellbore, causing additional expense and loss of revenue. Conventional nonexpandable well screens must necessarily be smaller than the wellbore in order to be conveyed therethrough, and so they are incapable of providing any radial support for an unconsolidated formation.

Previously proposed expandable well screens have associated therewith several problems, limitations and disadvantages. For example, they are typically not designed for contacting and providing radial support for a formation, and are thus unsuited for this purpose. Additionally, at least one previously proposed well screen assembly construction has a multi-layer configuration in which various tubular elements must be telescoped with one another and then inter-secured. The relative structural complexity of this previously proposed expandable well screen assembly, and the necessity of using multiple steps to fabricate it, undesirably increases its fabrication cost. Moreover, since the assembly portion outwardly circumscribing a perforated base pipe portion of the well screen has several layers, the maximum permissible unexpanded diameter of the base pipe is unde-

2

sirably reduced due to the necessity of limiting the outer diameter of the well screen assembly to a maximum value determined by limiting well dimensions. Due to this reduced unexpanded diameter of the base pipe, operational expansion thereof undesirably increases the expansion stresses thereon and reduces the maximum available expanded diameter thereof.

AS can readily be seen from the foregoing, a need exists for an improved expandable well screen, and associated fabrication methods, that eliminate or at least substantially reduce the above-mentioned problems, limitations and disadvantages of previously proposed well screen constructions as generally described above. It is to this need that the present invention is directed.

SUMMARY OF THE INVENTION

In carrying out principles of the present invention, in accordance with a preferred embodiment thereof, a specially designed well screen is provided and is useable in a subterranean wellbore as a particulate filtering structure. While the well screen is representatively of an expandable construction, it may also be advantageously utilized in applications where it is not necessary or desirable to expand the well screen. Additionally, principles of the present invention may be used in filtration applications other than in the representatively illustrated downhole well screen application.

According to an aspect of the invention, the well screen includes a perforated tubular base pipe coaxially circumscribed by a specially designed thin-walled tubular filter structure anchored to the base pipe and defined by a perforated tubular outer protective shroud having a tubular filter media sheet secured directly to its inner side surface. The construction of the filter structure facilitates the radial expansion of the well screen, provides it with a greater central flow area for a given maximum outer well screen diameter, simplifies the fabrication of the well screen, and reduces the fabrication cost of the well screen.

Preferably, the filter structure is of a metal mesh material and has relatively coarse radially outer and inner filter material layers between which a relatively fine intermediate filter material layer is sandwiched. The perforated tubular outer shroud member has a sidewall opening area percentage which is representatively in the range of from about 10 percent to about 30 percent, and is preferably about 23 percent.

According to a fabrication aspect of the invention in a preferred embodiment thereof, the tubular outer shroud/filter subassembly is formed by providing a flat perforated plate and placing on a side thereof a stack of individual metal mesh sheets. A diffusion bonding process is preferably used to bond the individual sheets to one another, and bond the sheet stack to the facing side of the perforated plate. Preferably, a single bonding process is used, although a first bonding step could be used to bond the sheets together, and a subsequent bonding step used to secure the bonded sheet stack to the perforated plate.

After peripherally trimming the flat plate/sheet stack subassembly to desired assembly dimensions, the plate/sheet stack assembly is deformed to a tubular configuration that defines the filter media-lined tubular shroud structure. A seam weld is placed along abutting edge portions of the now tubular perforated plate to hold it, and the tubular filter media structure which lines it and is directly secured to its inner side surface, in their finished tubular configurations.

The finished outer tubular shroud/filter structure is then placed coaxially around the perforated base pipe and suit-

ably anchored thereto, for example by welding the opposite ends of the shroud to the base pipe, to complete the fabrication of the well screen.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A and 1B are schematic views of a method embodying principles of the present invention;

FIG. 2 is a partially cut away simplified side elevational view of a partially assembled outer filter structure used in an expandable well screen embodying principles of the present invention;

FIG. 3 is a partially cut away simplified side elevational view of the assembled outer filter structure deformed to a tubular configuration;

FIG. 4 is a simplified side elevational view of a perforated tubular base pipe portion of the expandable well screen;

FIG. 5 is a partially cut away simplified side elevational view of the completed expandable well screen;

FIG. 6 is an enlarged scale simplified cross-sectional view through the completed expandable well screen taken along line 6—6 of FIG. 5; and

FIG. 7 is an enlarged scale simplified cross-sectional detail view of the area “7” in FIG. 6.

DETAILED DESCRIPTION

Representatively illustrated in FIGS. 1A and 1B is a method 10 which embodies principles of the present invention. In the following description of the method 10 and other apparatus and methods described herein, directional terms, such as “above”, “below”, “upper”, “lower”, etc., are used only for convenience in referring to the accompanying drawings. Additionally, it is to be understood that the apparatus representatively described herein may be utilized in various orientations, such as inclined, inverted, horizontal, vertical, etc., and in various configurations, without departing from principles of the present invention.

Referring initially to FIG. 1A, in the method 10, a screen assembly 12 including multiple expandable well screens 14, 16, 18 is conveyed into a wellbore 20. The wellbore 20 intersects multiple formations or zones 22, 24, 26 from which it is desired to produce fluids. The screens 14, 16, 18 are positioned opposite respective ones of the zones 22, 24, 26.

The wellbore 20 is depicted in FIGS. 1A and 1B as being uncased, but it is to be clearly understood that the principles of the present invention may also be practiced in cased wellbores. Additionally, the screen assembly 12 is depicted as including three individual screens 14, 16, 18, with only one of the screens being positioned opposite each of the zones 22, 24, 26, but it is to be clearly understood that any number of screens may be used in the assembly, and any number of the screens may be positioned opposite any of the zones, without departing from the principles of the present invention. Thus, each of the screens 14, 16, 18 described herein and depicted in FIGS. 1A and 1B may represent multiple screens.

Sealing devices 28, 30, 32, 34 are interconnected in the screen assembly 12 between, and above and below, the screens 14, 16, 18. The sealing devices 28, 30, 32 and 34 could be packers, in which case the packers would be set in the wellbore 20 to isolate the zones 22, 24, 26 from each other in the wellbore. However, the sealing devices 28, 30, 32, 34 are preferably expandable sealing devices, which are expanded into sealing contact with the wellbore 20 when the screen assembly 12 is expanded as described in further detail

below. For example, the sealing devices 28, 30, 32, 34 may include a sealing material, such as an elastomer, a resilient material, a nonelastomer, etc., externally applied to the screen assembly 12.

Referring additionally now to FIG. 1B, the screen assembly 12 has been expanded radially outwardly from its initial FIG. 1A configuration. The sealing devices 28, 30, 32, and 34 now sealingly engage the wellbore 20 between the screens 14, 16, 18, and above and below the screens.

Additionally, the screens 14, 16, 18 preferably contact the wellbore 20 at the zones 22, 24, 26. Such contact between the screens 14, 16, 18 and the wellbore 20 may aid in preventing formation sand from being produced, preventing the formation or zones 22, 24, 26 from collapsing into the wellbore, etc. However, this contact is not necessary in keeping with the principles of the present invention.

The use of an expandable screen assembly 12 has several additional benefits. For example, the radially reduced configuration shown in FIG. 1A may be advantageous for passing through a restriction uphole, and the radially expanded configuration shown in FIG. 1B may be advantageous for providing a large flow area and enhanced access therethrough.

Referring additionally now to FIGS. 2–7, an expandable well screen 36 embodying principles of the present invention is representatively illustrated in FIG. 5. The well screen 36 may be used for one or more of the well screens 14, 16, 18 in the method 10. However, it is to be clearly understood that the well screen 36 may be utilized in any other method without departing from the principles of the present invention. Additionally, if desired, the well screen 36 may be used in a nonexpandable application without departing from the principles of the present invention.

Well screen 36 (see FIG. 5) includes a generally tubular base pipe 38 (see FIG. 4), a generally tubularly configured multi-layer filter media sheet 40 (see FIGS. 5 and 6) coaxially circumscribing and outwardly overlying the base pipe, and a generally tubular protective outer shroud 42 (see FIGS. 5 and 6) circumscribing and outwardly overlying the tubular filter media sheet 40. The shroud 42 (see FIGS. 3–6) has openings 44 formed through a sidewall thereof to admit fluid into the well screen 36. Representatively, the shroud 42 has a sidewall opening percentage in the range of from about 10 percent to about 30 percent. Preferably, this sidewall opening percentage is approximately 23 percent. Fluid passing inwardly through the shroud openings 44 is filtered by passing inwardly through the filter media 40. The fluid then flows inwardly through openings 46 formed through a sidewall of the base pipe 38 (see FIGS. 4–6).

The well screen 36 may be radially expanded utilizing any of various methods. For example, a swage may be passed through the base pipe 38, fluid pressure may be applied to a membrane positioned within the base pipe, etc. Thus, any method of expanding the well screen 36 may be used without departing from the principles of the present invention.

Outer shroud 42 protects the filter media 40 from damage while the well screen 36 is being conveyed and positioned in a well. Additionally, if the well screen 36 is used in a method, such as the method 10 previously described herein, wherein the well screen is expanded into radial contact with a wellbore, the shroud 42 also protects the filter media 40 from damage due to such contact, and provides radial support to prevent collapse of the wellbore. Thus, the shroud 42 is preferably constructed of a durable, deformable, high strength material, such as steel, although other materials may be used in keeping with the principles of the present invention.

It will be readily appreciated that, when the base pipe 38 is expanded radially outwardly, the filter media 40 will be radially compressed between the shroud 42 and the base pipe 38. Because of differential expansion between the base pipe 38 and the shroud 42, it may be difficult or otherwise undesirable to maintain alignment between the openings 44 in the shroud and the openings 46 in the base pipe. This lack of alignment between the openings 44 and 46, and compression of the filter media 40 between the shroud 42 and the base pipe 38, could severely restrict the flow of fluid into the well screen 36. However, the filter media 40 includes features which completely or substantially eliminate this potential problem.

Specifically, as cross-sectionally illustrated in FIG. 7, the filter media 40 sandwiched between the perforated tubular base pipe 38 and the perforated tubular outer shroud 42 includes three layers of filter material—an outer relatively coarse layer 48, a middle relative fine layer 50, and an inner relatively coarse layer 52. The terms “fine” and “coarse” are used herein to indicate the relative size of particles permitted to pass through the filter layers 48, 50, 52. That is, the middle layer 50 filters fine or small-sized particles from fluid passing therethrough, while the inner and outer layers 48, 52 filter coarse or larger-sized particles from fluid passing therethrough. Each layer 48, 50, 52 may consist of one or more individual sheets of metal mesh material.

However, the inner and outer layers 48, 52 are not necessarily used for their filtering properties, although at least the outer layer 48 will filter larger-sized particles from fluid flowing into the interior of the well screen 36. Instead, they are used primarily to provide for flow between the openings 44, 46 after the base pipe 38 is expanded. For example, if the filter layers 48, 52 are made of a relatively coarse woven material, fluid radially entering the well screen 36 via the shroud openings 44 may relatively easily flow transversely through the layers 48–52 (i.e., generally perpendicularly to the radial direction of incoming fluid flow). Thus, fluid may flow into one of the shroud openings 44, flow transversely through the outer filter layer 48, flow inwardly through the middle filter layer 50, flow transversely through the inner filter layer 52 to one of the openings 46, and then flow inwardly through the opening 46 into the interior of the base pipe 38. Therefore, even if the filter media 40 is radially compressed between the shroud 42 and the base pipe 38, and the shroud openings 44 are not aligned with the base pipe openings 46, fluid may still flow relatively unimpeded through the filter media (other than the resistance to flow due to the relative fine middle filter layer 50).

According to a key aspect of the present invention, a unique method is utilized to fabricate the well screen 36 which provides it with a very desirable thin-walled configuration as well as reducing its complexity and fabrication cost. This fabrication method will now be described in conjunction with FIGS. 2–5.

As illustrated in FIG. 2, the outer tubular shroud 42 is formed from an initially flat rectangular metal plate 42a having the shroud perforations 44 formed therein, and having an inner side 54. The filter media structure 40 which, in the completed well screen 36 is of a tubular configuration, is initially a stack 40a of individual flat rectangular metal mesh sheets placed atop the inner side 54 of the flat metal plate 42. The mesh sizes of these individual metal mesh sheets are arranged so as to define in the stack the aforementioned relatively coarse filter media layers 48, 52 and the relatively fine intermediate layer 50.

Using a suitable diffusion bonding process, these individual metal mesh sheets are simultaneously bonded to one

another, and the stack of metal mesh sheets is bonded to the inner side 54 of the plate 42a. Alternatively, the individual sheets could be diffusion bonded to one another prior to diffusion bonding the stack to the plate 42a. While diffusion bonding is a preferred method of securing the filter media to the inner side 54 of the perforated plate 42a, other techniques could be utilized to secure the filter media to the plate, if desired, without departing from the principles of the present invention.

Preferably, the length and width dimensions of the rectangular wire mesh sheet stack 40a and the underlying flat perforated plate 42a are generally identical, and the sheet stack 40a is peripherally aligned with the underlying flat plate 42a, with the aligned peripheries of the stack and plate representatively extending along the dotted periphery line P in FIG. 2. After the diffusion bonding process has been completed, the periphery of the stack/plate subassembly is suitably trimmed from the dotted line P to the solid line periphery Pa shown in FIG. 2 to provide the plate/filter media subassembly with a finished periphery having predetermined final fabrication dimensions.

Next, as illustrated in FIG. 3, the flat plate 42 is suitably deformed to a tubular configuration, with the filter media structure 40 secured directly to its inner side 54 now also having been deformed to a tubular configuration and being circumscribed by the now tubular outer perforated shroud 42. To retain the shroud 42 and the filter media 40 which lines its interior in their tubular configurations, a seam weld 56 is formed along the abutting side edge portions of the shroud 42 and filter media sheet 40 to thereby complete the construction of the filter media-lined perforated tubular shroud 42 shown in FIG. 3.

After the fabrication of the shroud 42 is completed, the perforated tubular base pipe 38 (see FIG. 4) is telescoped into the interior of the shroud 42 (see FIGS. 5 and 6), thereby sandwiching the filter media 40 between the base pipe 38 and the shroud 42 (see FIGS. 6 and 7). The filter media-lined shroud 42 is then suitably anchored to the base pipe 38, such as by annular welds 58 (see FIG. 5) extending around the opposite ends of the shroud 42.

The securement of the filter media structure directly to the inner side 54 of the perforated shroud 42 not only simplifies and reduces the cost of fabricating the well screen 36, but also provides the screen 36 with other advantages compared to well screens of conventional constructions. For example, due to the thin wall construction of the outer filter/shroud structure 40, 42 the well screen 36 may have a larger diameter perforated base pipe 38 for a given maximum outer diameter of the well screen. Thus, when the well screen 36 is radially expanded (as, for example, in the previously described method 10), the resulting base pipe flow area is increased, and the expansion stress on the base pipe is decreased, compared to a conventional, thicker walled well screen having the same unexpanded initial maximum outer diameter.

Further, since the base pipe 38 is initially of a larger diameter than that of a conventionally constructed well screen having the same maximum outer diameter, the base pipe openings 46 can be sized based primarily on drainage efficiency considerations, as opposed to having to be sized based primarily to facilitate radial expansion of the base pipe.

As previously mentioned, while the screen well 36 is representatively an expandable well screen, it may also be advantageously utilized in a variety of applications in which it need not be expanded. Additionally, while the screen 36

7

has been illustrated and described as being a well screen useable in a subterranean wellbore, it will readily be recognized by those of ordinary skill in the filtration art that principles of this invention could also be utilized in a variety of other filtration applications if desired.

The foregoing detailed description is to be clearly understood as being given by way of illustration and example only, the spirit and scope of the present invention being limited solely by the appended claims.

What is claimed is:

1. A method of fabricating a filtration device, the method comprising the steps of:

providing a perforated plate member having a side;

placing a sheet of filter media against the side of the perforated plate member in a parallel relationship therewith;

forming a tubular filter structure using the step of deforming the perforated plate member, and the sheet of filter media, to a tubular configuration; and

telescopingly positioning a perforated tubular structure within the formed tubular filter structure.

2. The method of claim 1 further comprising the step of: securing the sheet of filter media to the perforated plate member.

3. The method of claim 2 wherein:

the securing step is performed using a diffusion bonding process.

4. The method of claim 2 wherein:

the securing step is performed using a sheet of filter media formed from a metal mesh material.

5. The method of claim 4 wherein the securing step includes the steps of:

stacking a series of metal mesh layers on the side of the perforated plate member, and

diffusion bonding the metal mesh layers to one another, and the stacked series of metal mesh layers to the side of the perforated plate member.

6. The method of claim 5 further comprising the step, performed prior to the forming step, of:

peripherally trimming the perforated plate member and stack of metal mesh layers diffusion bonded thereto.

7. The method of claim 2 wherein

the securing step is performed using a sheet of filter media having an inner layer of relatively fine filter material sandwiched between inner and outer side layers of relatively coarse filter material.

8. The method of claim 1 further comprising the step of: retaining the deformed perforated plate member and sheet of filter media in their tubular configuration.

9. The method of claim 8 wherein:

the perforated plate member has opposite side edges which are brought into close proximity in the deforming step, and

the retaining step includes the step of intersecuring the opposite side edges.

10. The method of claim 9 wherein:

the perforated plate member is of a metal material, and the intersecuring step is performed by forming a seam weld along the closely proximate opposite side edges of the deformed perforated plate member.

11. The method of claim 1 further comprising the step of: connecting the telescoped perforated tubular structure and formed tubular filter structure to one another.

8

12. The method of claim 1 wherein:

the providing step is performed using a perforated plate member having a sidewall open area percentage within the range of from about ten percent to about thirty percent.

13. The method of claim 1 wherein:

the providing step is performed using a perforated plate member having a sidewall open area percentage of about twenty three percent.

14. A method of fabricating a well screen for use in a subterranean wellbore, the method comprising the steps of: forming a tubular filter structure using the steps of:

providing a perforated plate member,

providing a sheet of filter media,

placing the sheet of filter media against the perforated plate member in a side-to-side relationship therewith,

deforming the perforated plate member, and the sheet of filter media, to a tubular configuration, and

retaining the deformed perforated plate member and sheet of filter media in their tubular configuration; and

positioning a perforated tubular structure and the deformed perforated plate member and sheet of filter media in a telescoped relationship with one another with the perforated tubular structure disposed within the deformed perforated plate member and sheet of filter media.

15. The method of claim 14 further comprising the step of: securing the sheet of filter media to the perforated plate member.

16. The method of claim 15 wherein:

the securing step is performed using a diffusion bonding process.

17. The method of claim 15 wherein:

the step of providing a sheet of filter media includes the step of providing a series of individual metal mesh layers, and

the securing step includes the steps of:

stacking the series of individual metal mesh layers on a side of the perforated plate member, and

diffusion bonding the metal mesh layers to one another, and the stacked series of metal mesh layers to the side of the perforated plate member.

18. The method of claim 17 further comprising the step, performed prior to the deforming step, of:

peripherally trimming the perforated plate member and stack of metal mesh layers diffusion bonded thereto.

19. The method of claim 14 wherein:

the retaining step is performed by forming a seam weld on the deformed perforated plate.

20. The method of claim 14 wherein:

the step of providing a sheet of filter media is performed by providing a sheet of metal mesh material.

21. The method of claim 14 wherein

the step of providing a sheet of filter media is performed by providing a sheet of filter media having an inner layer of relatively fine material sandwiched between inner and outer side layers of relatively coarse filter material.

22. The method of claim 14 wherein:

the step of providing a perforated plate member is performed by providing a perforated plate member having a sidewall open area percentage within the range of from about ten percent to about thirty percent.

9

23. The method of claim **14** wherein:

the step of providing a perforated plate member is performed by providing a perforated plate member having a sidewall open area percentage of about twenty three percent.

24. A method of fabricating a filtration device, the method comprising the steps of:

providing a perforated plate member having a separate filtration structure extending along a side surface thereof;

deforming the perforated plate member, and the filtration structure, to a tubular configuration and

10

telescopingly positioning a perforated tubular structure within the deformed perforated plate member and filtration structure.

25. The method of claim **24** further comprising the step of: retaining the deformed perforated plate member and filtration structure in their tubular configuration.

26. The method of claim **24** further comprising the step of: connecting the telescoped perforated tubular structure and deformed perforated plate member to one another.
